...and still serves as a sergeant or that he has  
...of my life into this

Newman, Friedman and Hanger compared the intellectual abilities of twins by means of various intelligence tests. On one of these IQ tests (Binet's) the average difference between one twin and his reared-together twin amounted to 3 points. But when they were reared apart the difference increased to 8 points.

Twins reared together showed a greater similarity in personality than twins reared apart. This finding was supported by the fact that the twins reared together had a higher correlation of personality traits than the twins reared apart. The Stanford experiment showed the average difference between twins reared together to be less than the difference between twins reared apart. This result was more alike than the previous ones. The result of the environment is much more important in the test of motor ability and emotional balance. The experiment assumed the major role more than half the difference between twins is due to environmental factors. The result is that the twins reared together are more alike than the twins reared apart.

[illegible]

Studies of other investigators have shown that such important behavior traits as criminality are to some extent influenced by heredity. For example, prisons were coined for members of twin pairs. Where the twins came from the one egg type then in many cases the other twin was found to be a criminal or had a criminal record. Where the parents of the two egg type the majority of the twins did not become involved in any kind of crime. Of course, there may still be a social influence on the twins. The facts justify the conclusion that even a certain environment predisposes of some hereditary constitution are more likely than others to fall into anti-social behavior.

For the Child on

The dependence of mental traits on both heredity and environment can be demonstrated by studies on foster children. When children are distributed to foster homes it is unlikely that some of them will be placed in more favorable than others in less favorable environments. One can then compare the intelligence and characteristics of children who have lived in different environments. A major investigation recently completed by the University of London is the following. Suppose for the sake of argument that the intelligence of a group of children is determined by the environment. The intelligence of foster children should then be proportional to that of a child living in the same family. If on the contrary intelligence were due to heredity alone there would be no consistent relationship between the intelligence test scores of foster and of own children. The actual data on a wide range between the extremes of foster children shows however that intelligence is inherited but that the environment has a large influence. It thus points to the importance of the environment. But it is not the whole story. In the most favorable foster

[illegible][illegible]

Gregor Mendel worked in the monastery of St. Thomas in Brno, Moravia, in 1857 to 1869. He was a monk and a naturalist. He was interested in the laws of heredity. He conducted experiments on pea plants. He discovered the laws of heredity. He published his results in 1866. His work was not appreciated until 1900. He is now considered the father of genetics.

periment on heredity cannot be used as a method of study on human beings. Large domestic animals, cattle, horses, or sheep are also unfavorable because of low fertility, slow breeding, and great expense of raising large numbers. The need to observe thousands of individuals of known parentage sometime through dozens of generations has led students of heredity since Mendel's time to choose for experiments the rapidly breeding vinegar fly (*Drosophila*), Indian corn, mice, and rats, wheat, rapeseed, and many tobacco plants and more recently mold and other microorganisms. Enough of these have been used to illustrate the theory of particular traits that Mendel's principles apply to them.

### Mendel's Law

The essence of Mendel's discovery lay in his identification of the unit of heredity. The essence of the gene were the first living units to be discovered which are comparable to the atoms or molecules upon which our understanding of the non-living world has been based. The discovery of them has had a fructifying effect upon the whole of biology comparable to the effect of the atomic theory upon the physical sciences.

How can one apprehend such living units which cannot be seen? In particular how can one prove the unit to be discrete, hereditary particles endowed with the kind of individuality which is so useful to a biologist? First, one must choose a material in which specific visible characters of plants such as flower color, seed shape, etc., appeared in the offspring. His method was so simple that it can be repeated by anyone who can observe the results of controlled mating in any kind of animal or plant. When a plant of pure purple flowered variety was crossed with a white flowered plant, the first generation always yielded only purple flowered plants. When these purple flowered plants were allowed to produce their progeny, these usually produced about 1/4 of

by Mendel found that this is exactly what Mendel discovered in every cross that he made. Let us give his sufficient condition a name. Always the mixture between two hybrid (F<sub>1</sub>) hybrid mixture with itself by self fertilization) produced offspring of which about 1/4 were like one of the parents (F<sub>2</sub>) were like the hybrid parent and 1/4 were like the other parental type. This is known as the Mendelian segregation ratio of 1:1:1:1. Mendel found that it proved that the parent of each of the cells of a hybrid could transmit or not only one of the two alternative characters and that half of the excellent transmission of one of the characters and half of the transmission of the other character. Every single one of these alternative combinations of one unit will be found to be found in the proof of the existence of the unit character and thus as the revolutionary way to introduce it by Mendel.

Model found that this theory held true for every  
character and he studied in the botanical  
it been confirmed by experiment with the  
of other kinds of animal plants. In all cases  
it be shown that the genes contributed to the  
of the parent do not mix but recombine  
the different cells of the hybrid so that the  
of the character of the parent will re-  
appear in the offspring. This is the hybrid  
of the body of the hybrid known  
as the genotype.

The portion of the text which is in parentheses is not part of the original text. The original text is as follows:

It is a very common mistake to think that the only way to get a good result is to work hard. In fact, the only way to get a good result is to work smart. This means that you should plan your work carefully and then execute it efficiently. This is the key to success in any endeavor.

100 only in families in which at least one

ordinary sowers and the c  
 ones short and ordinary in about equal numbers just  
 s Mei del found in his test cross of a hybrid to a recessive  
 ve This means that virtually all short sown cre' persons  
 re hybrid (heterozygous) and for the same reason  
 c sons & other rare dominant defects are nearly  
 always hybrid and transmit the defect to about half of  
 their children. Sometimes however the abnormal gene  
 occurs in an isolated village or valley where people are  
 likely to marry neighbors and relatives and the it may  
 happen that two with the same abnormality marry. A  
 case of this sort was recorded by two Norwegians in investi-  
 gators who found a family in which both father and  
 mother had the short fingered trait. Two children were  
 born one short fingered the other a cripple  
 with three or four it. All the children were short  
 fingered. It did not like cry. It all of it  
 I fear the short fingered character getting in the  
 lineage from both father and mother but the hand-  
 paws were severe it said a child all of it never  
 live to adulthood. We should therefore not expect to  
 find any of it what is pure (homozygous) for such an  
 abnormality

C b nati r s c f C e es

In the character of the letters for study  
and have picked out one pair of characters for study  
which are the many other characters which  
always differ. Eventually, we should face the  
fact of following more than one line at a  
time and discover how to deal with pairs of characters  
which are not to be confused. We would like  
to know how to find the right way to do this. By  
the use of the letters in the list, we can find the  
two or three letters which have all the law of

number of human character differences is much greater than three so the number of combinations must be very large

The following table shows the number of types which theoretically must appear among the hybrids when the parents differ in a certain number of dominant genes

Gene differences	Types in the progeny
1	2
	4
	6
1	16
5	32
10	1024
0	10876
0	107181
n	

If the number of distinct types (gene combinations) is to be thousands and let parents differ in genes to more than a million and to more than a billion with 30 gene differences. With 31 gene difference it becomes about equal to the total number of men now living in the world which is estimated close to 200 millions. With still greater numbers of gene difference the numbers of possible gene combinations become immense. With 100 genes the number of theoretically possible gene combinations is of the same order as that of the electron and protons in the universe as estimated by scientists. Such calculations may seem meaningless because certain than that only an ex-

hybrid produces 1024 distinct types of sex cells and is capable of engendering that many different types of offspring. We see then that the chance of two brothers or sisters receiving the same hereditary endowment from their father or from their mother is small. The chance that they receive the same endowment from both parents is quite negligible unless of course the brothers are identical twins. As we now know identical twins arise from a single egg and have the same genes.

How many genes there are in man is unknown but it would seem reasonable to believe that man has at least as many as the earth fly *Drosophila*. To be sure the number of genes is not precisely known even in that insect which has been studied more than any other animal but it is more plentiful in a *Drosophila* than several thousand pearls in many a ten thousand genes in each sex cell.

To illustrate the difficulty of counting the genes in any animal or plant even the careful biologist the method through which we learn about the existence of the genes is still far from perfect. Mendel observed the segregation of the purple and white flower color in the offspring of a hybrid between the purple and white varieties and concluded that the pea plant must have a gene for flower color. Our knowledge of the genes for human PTC for eye color for albinism and for brachydactyly in man comes from observations on the distribution of characters and from statistics. Brown and blue eyes, albino and non-albino, short and tall, normal fingers in selected human families. But man knows that all the persons in the world or know it to be are purple (or blue) or white. PTC is never been reported or tested. The existence of the genes for the flower color in pea is for the PTC in man would not even be suspected. For other works we find out about the existence of genes for genes only if we observe and find that they differ with respect to that trait and finally state that if such individuals are crossed. The segregation in the offspring can be predicted by the laws of Mendel.

Calculation errors are inevitable in this hybrid calculation. It is a very conservative estimate of the future probability. Now such a

ular environment are perpetuated in the descendents and eventually become established as the dominant form of that species. The least combinations of genes gradually disappear through the perpetuation of the more effective. The supply of variation is kept up by the process of mutation which is set forth below. occasionally changes old genes into new ones. The number of new combinations of genes which thereby become possible practically unlimited and there is certainly no limit to evolutionary development.

is that no matter what may be the proportions of taster and non-tasters in the population of a nation or country, the proportions will persist indefinitely. Of course this is true only for the genes  $T$  and  $t$  and is applicable for the ability or inability to taste  $TC$ . But for any other genes as well, provided only that parents who do not carry these genes live all out their life and have only the same kind of children. The genes found commonly in a population will remain just as common centuries later and rare genes will continue rare. Contrary to what sometimes is said, all recessives seem to imply a dominant in the next generation but the recessive or the recessives crowd out the dominants. The frequency of the genes tends to remain constant.

### The Carrier

We now turn to the question of the carrier of the dominant and recessive genes. If we take the case of the ability to taste  $TC$ , we find that the proportion of the population that is taster is about 75% and the proportion that is non-taster is about 25%. The carrier of the dominant gene is the person who has one dominant and one recessive gene. The carrier of the recessive gene is the person who has two recessive genes. The carrier of the dominant gene is the person who has one dominant and one recessive gene. The carrier of the recessive gene is the person who has two recessive genes.

As shown in the Appendix it is easy to calculate the frequency of the genes in a population of a population of 1000. The frequency of the dominant gene is 75% and the frequency of the recessive gene is 25%. The frequency of the dominant gene is 75% and the frequency of the recessive gene is 25%.

of persons showing the effects of the gene. Since non-tasting is recessive to tasting, the proportion of the gene for non-tasting in the gene pool is the square root of the percentage or about 15% ( $\sqrt{.25} = .55$ ) of all the genes of the population. It is easy to find the proportion of persons in a population who will show the effects of a gene if we know the frequency of that gene in the gene pool. The frequency of persons showing the effects of the recessive gene is the square of the frequency of the gene. For example, if a recessive gene has a frequency of 15% in the population, the frequency of persons showing the effects of the gene is  $.15 \times .15 = .0225$  or 2.25% of the population. It is the same for the dominant gene. If the frequency of the dominant gene is 75%, the frequency of persons showing the effects of the gene is  $.75 \times .75 = .5625$  or 56.25% of the population.

We can then predict with confidence that the proportions of the eyed and the eyed persons in New York City will be found in New York some centuries hence unless one or more of the following things happen:

- (1) Relatively more blue-eyed (or brown-eyed) people come to New York or leave New York to live in other places.
- (2) Blue-eyed (or brown-eyed) people are more likely to have over the other type of health or longevity of life or fertility or other qualities which result in a higher birth rate than the other type.

### Conclusion

#### New Genetics by Mendel

We have now to sketch a preliminary outline of the problem of the origin of the variety of the eye which is found in the population. It is not difficult to understand why the eye is of two forms. It is not difficult to understand why the eye is of two forms. It is not difficult to understand why the eye is of two forms. It is not difficult to understand why the eye is of two forms.

condition and that all the defectives die before they can have children. The genes present in the defectives are being lost and their number in the population would decrease.

Un fortunately there is no reason to believe that he  
 re is any disease in process of disappearance. In  
 fact some figures make it look as though such diseases  
 are coming more frequent but this is probably a false  
 impression due to improved statistics and not to a rise  
 in the disease. The few deaths of a century ago most  
 of them were of the same nature as the statistics are available

At this time we have been studying the mutation rate in the laboratory. We have found that the mutation rate is very low, about one in ten million per generation. This is much lower than the mutation rate in nature, which is about one in a hundred thousand per generation. The reason for this difference is that in the laboratory we are able to control many factors that influence the mutation rate in nature.

1. The first thing I noticed when I stepped out of the car was the heat. It was a sticky, oppressive heat that seemed to wrap around me like a heavy blanket. I had heard that the weather in the South was terrible, but this was something else entirely.

I own Anna from normal colored parents proved to be piebald that is her skin was irregularly spotted with white. She had fifteen children by a normal colored man eight of which were also piebalds. At least five of these are known to have had in turn some piebald progeny while no piebalds were born to their non piebald brothers and sisters. It is fairly sure that the piebalds in this family are from a sex cell which con-

try did it not present in the pedigree appeared suddenly in a single child born of normal parents as recorded in the medical literature. It is certain that at least some of these instances represent authentic mutations.

I precisely why mutations occur in man or in other organisms we do not know as yet. Mutations appear more frequently in the offspring of individuals treated with X-rays, high temperature and some chemicals. But mutations also occur without any treatment. For example, we know they just happen in every 100,000 human cells.

ently arose from such a lineage through her daughter and grandson to the present day. She remarked that she had been a carrier of a family mutation gene eventually to the physician to save

When all or a part of the victims of an inherited disease regularly die without leaving progeny and nevertheless the disease does not become less frequent because the supply of life

through death of  
to the number of these bees arising by mutation  
altogether the income balance the disease becomes

neither more nor less frequent with time and what is known as the state of equilibrium is established.

We can be absolutely sure that hereditary diseases and defects have not been brought about by the effects of a civil life. It is absurd to say that these diseases and defects indicate degeneration of the species. Natural mutations of wild animals as well as domestic animals carry numerous beneficial genes. There is no doubt that such degeneration has accompanied all evolution including progressive evolution.

### The Grim and the Chaff

As stated above the occurrence of mutations is regarded in modern biology as the fountainhead of all evolution. In every generation the process of mutation adds a variety of genes to the gene pool. Next sexual reproduction and Mendelian recombination bring the genes into new combinations. And finally natural selection is the great filter which separates the grain from the chaff, the process by which the material is

collected into natural selection according to the material's fitness for itself.

A seemingly very grave objection to this theory is that not all variations occur at the same rate. We have seen that mutations which produce such serious hereditary diseases as phenylketonuria are much less frequent than those which produce such harmless variations as the ability to digest milk. If we are to describe more exactly the nature of the mutations which would play a part in the evolution of the human race, we must be able to tell whether a variation is harmful or at least deleterious to the carriers. But harmful mutations can only lead to the extermination of the species, so how can such mutations survive over the fitness of their possessors?

The answer to this puzzle is simple enough. In the course of human evolution have so far been a part of the evolutionary process. The fact is that the carriers of a particular gene are not necessarily the only ones to be

high in others. In man, for instance, and especially albinotic individuals often suffer painful sunburn. While persons with pigmented skin are relatively protected from this danger. On the other hand there is some evidence that light skins permit their possessors to secure a supply of vitamin D (the sunlight vitamin) more easily than do dark skins. Are then the genes which make the skin white useful or harmful? The question is evidently meaningless if the environment is not specified. Light pigmentation may be useful in countries with a free sun line and dark pigmentation in climates with strong sunshine. The ability to withstand intense heat is very useful in the jungles of Africa or of Brazil, but it is resistance to cold which counts most with the inhabitants of Greenland or Tierra del Fuego. A group of Indians transplanted certain plants native on the seacoast of California to a high mountain and found that the transplanted individuals died because of the inability to stand the long mountain winters. On the other hand, when races of the same plant species which grow naturally on a mountain meadow were transplanted to the coastal dry ground very susceptible to attacks by a disease-producing fungus (mildew).

Some people like to believe that all men are born not only equal in ability but also biologically alike. But facts show clearly that people are not alike. In man as in other biological species which reproduce sexually actually no two individuals have the same heredity (and no two identical twins excepted). Biological differences are quite compatible with equality. Equality is not a biological but an ethical principle. And in the light of the evolution theory we can understand why men are not all alike. It is because the world in which we live is tremendously diversified. It has plains and mountains, woods, prairies and deserts, rich and poor soils, tropic islands and arctic tundras, places where food is plentiful and others where it is difficult to come by. When a species of life exists with a variety of conditions it usually evolves a variety of types that

if the first recessive mutation does fix in a natural community in the aa class while still being in the A class. Now it happens that children affected with recessive diseases are abnormal in the first months to parents who are only heterozygous for the defective gene and to them the child is normal. But a parent has to be only heterozygous for a gene just to be able to say that the child is a carrier for the disease. It is therefore not possible to say that a child is affected if the parents are heterozygous for the defective gene. It is only possible to say that a child is affected if the parents are affected themselves.

[illegible]

$\frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} f(x) e^{-x^2} dx = \frac{1}{\sqrt{\pi}}$

It is statistically true that if a gene for a recessive disease or abnormality is rarely all of the genes will be found in *AA* people who are themselves perfectly normal although of course they transmit the disease to the offspring. In England for example about one in every 1000 people is an albino. This means that in the gene pool a little more than ninety nine per cent of the genes are *A* (the ones for normal pigmentation). If it is one per cent *a* (the gene for albinism) it is certainly not as much as half per cent of people who are normally pigmented carriers of albinism. The frequency of the *a* gene is 85 times as much as the *A* gene.

Now suppose that we select individuals to have a race of people who can all taste LTC. Taste blindness for LTC is to be regarded as harmful if it is passed on to the people from the race to good (usually does the case) to LTC are of course the genetic error inferior to the others cannot. Therefore the race should stay with others to prevent the taste blind people from having children to taste blindness believes in heredity as a recessive trait all the taste blind persons are in the aa category. Thus we can stop all of the genes in the aa people from going on to the next generation. But the gene for taste blindness is found in the people as well as in the people. It is hard to be thorough as many as we are people. This even if all the taste blind people are taken the gene for taste blindness will be present in the population. Some taste blind individuals will still be the next generation.

The first of these is the fact that the population of the United States is growing rapidly. In 1950, the population was 150 million. In 1960, it was 170 million. In 1970, it was 200 million. In 1980, it was 220 million. In 1990, it was 250 million. In 2000, it was 280 million. In 2010, it was 310 million. In 2020, it was 330 million. In 2030, it is projected to be 350 million. In 2040, it is projected to be 370 million. In 2050, it is projected to be 390 million. In 2060, it is projected to be 410 million. In 2070, it is projected to be 430 million. In 2080, it is projected to be 450 million. In 2090, it is projected to be 470 million. In 2100, it is projected to be 490 million.

Initial	Frequency
1	21
2	6
3	1
4	8
5	11
6	10
7	10

One can see from the table that the frequency of the various types of defects is not too high. If so far as the frequency of the defects is concerned, the frequency of the defects is not too high. If so far as the frequency of the defects is concerned, the frequency of the defects is not too high. If so far as the frequency of the defects is concerned, the frequency of the defects is not too high.

A table of the frequency of the defects is given in the table. The table shows that the frequency of the defects is not too high. If so far as the frequency of the defects is concerned, the frequency of the defects is not too high. If so far as the frequency of the defects is concerned, the frequency of the defects is not too high.

yearly) to reduce the proportion of abortions in the population to 1. If the frequency

Now the frequency of the above table is compared with the frequency of the above table. Where a race is given in the table, the frequency of the above table is compared with the frequency of the above table. Where a race is given in the table, the frequency of the above table is compared with the frequency of the above table.

As we have already stated that the sterility of the population is not a single factor, it is of course doubtful if any proportion could be ascertained in practice. But even if we were to do so, it would be complete coincidence with a similar proportion. The dependence of the effects of the above table on the above table is not a single factor, it is of course doubtful if any proportion could be ascertained in practice.

1. The frequency of the above table is compared with the frequency of the above table. The frequency of the above table is compared with the frequency of the above table. The frequency of the above table is compared with the frequency of the above table. The frequency of the above table is compared with the frequency of the above table.

of negative values. The frequency of the above table is compared with the frequency of the above table. The frequency of the above table is compared with the frequency of the above table. The frequency of the above table is compared with the frequency of the above table.

It is very true in fact that we do not know  
 exactly how many defective genes are in the  
 population. We have only a rough estimate of  
 the percentage of the population that is affected  
 by certain defects. For example, we know that  
 about 1 in 1000 people are affected by  
 certain defects. This is a very low frequency  
 of occurrence. However, it is not always true  
 that the frequency of occurrence is low. For  
 example, certain defects are more common in  
 certain populations than in others. This is due  
 to the fact that certain defects are more  
 common in certain populations than in others.  
 This is due to the fact that certain defects are

[illegible]

Darwin knew that his hypothesis of pangenesis was just a guess, this is why he stressed its provisional character. But it fulfilled the most important function of any scientific hypothesis: it stimulated a great amount of research and experimentation. In at least thirty years, his hypothesis has been taken from the me of Wissenschaft to Galton, and from the me to the most recently made studies on plants and animals to see whether acquired characters are ever inherited. The number of believers in this continually dwindled steadily because of the outcome of the experiments on inheritance of acquired characters, as so the formerly negative

The rediscovery of Mendel's laws at the development of genetics in the current century have produced a much better understanding of the mechanism of heredity in various animals in Darwin and Weismann's day. In the light of this understanding, we can clearly see the acquired characters are not inherited. This is because heredity is transmitted through genes and not through blood mixture (see Chapter 9). Genes pass from each other by dividing their chromosomes and not through the transmission of the reproductive material to the cells. The inheritance of the traits of the cells is not affected by the use of the food. The inheritance of the traits is not affected by the use of the food.

*İşlenmiş Midekürü esin*

An organism named Lysenko has recently secured for himself a great deal of power in the Soviet Union and much notoriety else here by his attacks on all other genetics and by his advocacy of the so-called "Mendelian" theory of heredity. Lysenko's views have in recent years spread so much in the popular press that he has aroused a much passion that we are forced to get them a fair consideration despite the fact that they are highly cannot be taken seriously by anyone familiar with the fundamentals of modern biology. For the queerest thing about Lysenko is that he has produced no new theories either right or wrong ones. His assertions that acquired characters must be inherited differ only in greater emphasis from those made by the immediate followers of Lamarck and Darwin in the last century. Lysenko has revived Darwin's hypothesis of pangenesis, although he does not call it by that name and does not acknowledge Darwin's authorship. Furthermore, he denies with out cogent reason the validity of Mendel's discovery and of the theory of the gene built on them. Lysenko also denies the chromosomal theory of heredity with which he does not seem to be very familiar. If the word reaction means retreat to an outworn stage of the development of a society or a science Lysenko's progressive dialectical theories are certainly reactionary since they simply do away with at least half a century of biological thought.

Iysenko claims that his negation of modern biology is supported by the work of Michurin (18 193 ) a successful fruit tree breeder whom a propaganda campaign in the Soviet Union now resells to students as an alternative to Michurin's requestonably held

use a number of very valuable methods. Most of us was an amateur in biological science. Although in his work he followed the classical methods used by al-

## Can Genes Be Changed by the Environment?

Bodily or mental traits acquired during an individual's life are not transmitted to his offspring. The relative frequency of the various inherited characters are inherited. However, it is widely understood in modern biology that the hereditary genes are unchangeable or stable from the environment. It must be added

to Lysenko the pretext to use are the mystical and even pseudo-scientific

That genes can be changed by the environment is indeed self-evident. Although the exact chemical make-up of the genes is not known, they consist of a kind of chemical substance (nucleo-protein) which is extremely complex and can undergo changes in many ways. To give a crude example, when you boil eggs for your breakfast, you actually change the genes contained in those eggs by heat. Or you can kill the sex cells of any organism by any one of a great variety of poisons, and this will also change the genes carried in the sex cells. The important problem is evidently not whether genes can be changed, for they clearly can be, but what are the consequences of the change. And here it appears that the modern geneticist is in a bit of a predicament. It is true that the

such it is not likely to be spoiled by any other factor. It expects to prove itself by poking a stick into it. The change in the gene which are inherited to us is really a very peculiar kind. They are not retained, but they are reproduced by themselves from outside materials, from food. Such change

called mutation (see Chapter 4) and they occur relatively rarely. The statement that the hereditary of an organism cannot be changed easily means that only that we do not yet know how to make the genes of a certain kind to be able to make them in a state

but it is not likely to be spoiled by any other factor.

10 Heredity Race and Society

Caucasian or white

Mongol or yellow

Negro or black

American red

Malay or brown

It is a biological classification which is based on the differences between the physical characteristics of the different races.

Of the various races, the most important are the Caucasian, the Mongol, the Negro, the American, and the Malay. These races are distinguished by their physical characteristics, such as skin color, hair, and eyes.

The Caucasian race is the most numerous and is found in Europe, Asia, and Africa. The Mongol race is found in Asia and is characterized by yellow skin and black hair.

The Negro race is found in Africa and is characterized by black skin and curly hair. The American race is found in North and South America and is characterized by brown skin and wavy hair.

The Malay race is found in Southeast Asia and is characterized by brown skin and black hair. These races are the result of different evolutionary paths and are adapted to their respective environments.

The study of race is important for understanding human evolution and the development of different cultures. It is also important for understanding the social and economic differences between different racial groups.

It is important to note that race is a social construct and is not a biological reality. The differences between different racial groups are the result of social and cultural factors, rather than biological ones.

Therefore, it is important to understand the social and cultural context of race, rather than focusing on biological differences. This understanding is essential for promoting social equality and understanding the complexities of human society.

The study of race is a complex and multifaceted field. It requires a deep understanding of human biology, anthropology, and sociology. By studying race, we can gain a better understanding of ourselves and the world around us.

physically the inhabitants of Denmark and Sweden more than they do the South Germans who in turn are physically similar to some Frenchmen, Czechs and Yugoslavs. You will not be able to distinguish by sight some Swedes, Finns and Russians, yet they speak very different languages.

It is very easy to be deceived by differences amongst peoples even in facial features, in their dress and in their customs. The hair of the different races seems dissimilar as it grows from the very population from which they are descended. If one were to arrange a guessing contest as to what race certain particular Europeans belong to, it would have to be conducted either without any clothing or decoration at all or with the neutral uniform of dress and color. Indeed the soldiers and uniformed members of the city spread throughout all populations. Racial differences have often been inferred from character and traits as these.

The issue of race for political and military purposes has been the term used into such disregard that it is very difficult for scientists to propose to abandon the term altogether. It is applied to human groups. It is sure that the same may say by the human race, we certainly do not mean the same thing as the races of man, nor does the latter convey the same meaning of race as intended in discussion of the races of Europe and yet there are human entities for which the term race if properly used could stand.

If one is concerned with the use of the word which the race notion or racialist uses of the notion have brought about then it might be better to convey the idea of race in other words. Some have used ethnic group, place of race but unfortunately ethnic is still rejected as it is only applicable for race people. It is not correct to call it a race as it is only a social term.

Any one can find the limits of human variation from the fact that the American population is a mixture of different racial groups.

incident if the person whose race we wish to determine  
 belongs to a particular tribe or people directly with the  
 cause for any error. If we know any measure  
 of the race for all of the two myself  
 the in the predicament that naturally exists  
 or on an of any race anywhere there is to the  
 itself. Since every individual differs from any other  
 individual everyone belongs to his own special race  
 but to say that makes the race concept absurd.  
 Not only adults but also whole groups of people  
 frequently difficult to place in any one race. Our  
 about No dies come from our acquaintance with  
 various and several and our ideas about the Al  
 from observation is on southern Chinese No  
 abstrus of northern and central Chinese are on  
 the same intermediate between the two. Al  
 among the studied and they found who are  
 the typical Nordic and the Alpine as can  
 found any here. What race these people belong  
 We may try to escape the difficulty by saying that  
 the Nordic and Alpine elements in their  
 only that the physical nature of the body is  
 a no more reflection of his life than leaves  
 and or difficult no less serious than the first

# Are Races?

If you say that something is a mixture you imply  
 the reduction which have been used together  
 for exist some her or have existed in the past. But  
 here the first Nordic and the Alpine pure Mediter  
 ranean? What is your going to say that only  
 exists if any individual traits of the body conform to  
 the notion of racial purity and no more  
 the body you will meet a head full of the  
 the person in the city of New York but you  
 find there a few any individual brown eyes  
 red hair there is not to be said that  
 the of the Northern European are as  
 as to the city than are the blond bloods

Only blue eyed blond are met with occasionally among  
 the Americans and the are the first

As a last resort to the my opinion that although no  
 countries inhabited by pure Nordics and pure  
 Alpines (or by any other pure race for that matter)  
 exist at present such countries did exist in the past.  
 The assumption is actually implied in most popular  
 discussions of the race problem. Back in some distant  
 Golden Age people religiously kept their race pure  
 and this made them strong and wise. Recently they al  
 lowed themselves to become mixed or mongrelized  
 and the result of of humanity is about to swallow us as  
 a consequence. Such notions are however definitely  
 refuted by scientific data. The mixture has been going  
 on during the whole of recorded history. Incontrover  
 sible evidence from statistics on fossil human remains  
 shows that even in prehistory at the very dawn of  
 human history of different stocks (at least occasio  
 nally) took place. Marked it as it has been and still is  
 a mongrel lot.

To be sure the growth of the world's population in  
 the last several centuries coincides with the level  
 of the means of travel and communication has  
 enormously quickened up the process of mixing of the  
 human races. Mixing of at least closely related races  
 (such as those found in different European countries)  
 appears however to be biologically desirable rather  
 than the reverse. A gradual increase of the average sta  
 re has been going on in the civilized countries of  
 the world during the last hundred years. This  
 becoming fiercer due in part to immigration of  
 the colored is and in latter immigration but in part  
 also to the life of the workers who in the past sepa  
 rated different peoples so that tall genes could spread  
 more widely. However that may be not only the  
 more certain than that pure races in the past never existed  
 and can not exist.

It is impossible that the population of a country at the  
 or an individual selected from any number of the  
 outside at all allowed to breed for a single generation is

of this some of us have blue and others brown eyes some have prominent and others flat noses some are tall and others short Such differences are a course common among people of the same country state town members of a family and even brothers and sisters We do not suppose that every person with blue eyes belongs to a different race from everybody with brown eyes It would be absurd to do so because blue and brown eyed children are frequently born to the same parents It happens however that certain genes are more frequent among the inhabitants of some countries than of others Thus blue eyes are very common in most parts of the United States but rather rare in most parts of Mexico It is this and similar differences which make it possible to say that the inhabitants of the United States are in general racially distinct from the inhabitants of Mexico Races can be defined as populations which differ in the frequencies of some gene or genes

### Blood Cross

Now let us try to understand the racial subdivision of mankind in the light of this definition One of the most interesting human genes is that which determines the blood group to which each person belongs It was of practical importance to work out the inheritance of this gene because of its relation to blood transfusions One of the first things of blood is one person to another so that the distribution of the various types of this gene amongst the different parts of the world is not very well known On the first of this whole subject we have seen that the blood transfusion is a very important thing in the life of every race and that the various types of the gene are distributed in different proportions in different parts of the world The various blood groups are known to the composition of the

blood. The groups are known as O A B and AB Blood transfusion between members of the same group is safe Blood from people of group O can safely be given to persons of any group hence group O people are called universal donors Persons of group AB are called universal recipients since they can safely receive blood from any other person But A blood can not be given to O or B persons B blood should not be given to O or A persons while AB blood causes trouble if transfused into O A or B persons To which group a person belongs can be found out by drawing a drop of blood and mixing it with some drops of blood (the fluid part of the blood from which the corpuscles have been removed) of persons known to be of A and group B If your blood corpuscles clump together or agglutinate in B serum you belong to group A If they clump in A serum you belong to group B If they clump in both A and B serum you belong to group AB while if no clumping takes place you belong to group O The whole examination takes only a few minutes and the clumping is perfectly clear under a microscope or with practice it can be seen with the naked eye

### Genes and Geography

Within the last twenty to thirty years the study of genes in all parts of the world has been extended The most interesting result of this study has been that with few exceptions nearly every group of people has been found to consist of a mixture of the four blood group human races the relative mixture of persons within the unit varies with each of the four groups Universal donors are found in every race and are generally the most common type group A is also common while group B is less common The table below shows the frequency of the blood groups in different parts of the world

PERCENTAGES (IN PER CENT) OF INDIVIDUALS OF THE FOUR BLOOD GROUPS AMONG THE INHABITANTS OF DIFFERENT COUNTRIES

[illegible]

used by anthropologists in characterizing races. A favorite trait of this sort has been head shape. Heads do not vary as blood types do in sharply defined alternative categories. The variations are continuous from very long and narrow to very short and broad, with all intermediate shapes, and the differences probably depend not on one or two but on many genes. Heads of all shapes—long, medium and round—occur in all European countries just as the four blood types appear in all of them, and as the blood types the proportions of persons with the different head shapes vary from country to country and from district to district. Roundheads are common in Central Europe—from France through southern Germany and northern Italy to Czechoslovakia, southern Poland, Hungary, Yugoslavia and Albania. The inhabitants of the British Isles, most of Scandinavia and the Baltic provinces of Russia are mostly longheads. Another region of longheadedness is found in the South—Portugal, Spain, southern Italy. Between the regions in which roundheads or longheads predominate at all is most of Russia, the population is mostly intermediate in head shape. People with round and with long heads are found also outside of Europe. As examples of roundheads there are Acheans in Java, American Tahitians in the South Seas and many tribes in Central Asia and in Siberia. Among the longheads are many Eskimos in America, the Australoid Chelleros, many Africans and some Indians in Asia.

Now the evidence should be apparent why different scientists who attempted to classify mankind emerged with such different collections of races. It is because the genes for different human traits vary quite independently of one another. If we were to classify Europeans according to the blood groups we would probably have Western race as 1 race as English French, Italian, etc. and Spanish who have little blood group B. Middle race with moderate amount of B and Indian race (Indo-Blacks, Malays and Finns) in which group B is frequent according to the shape of the

It turns belong to the same race. Races merge into each other geographically. If we travel from Norway southwards through Germany, Switzerland and Italy we find that the blue eyed individuals become gradually less frequent and the eyes more frequent. But now there is a break or a change on the borders of which people are clearly so different that we can say that here the northern race ends and the southern one begins. If we look at it, but three races a north, a central and a southern the difficulty becomes even greater. There is instead of one indefinite boundary a change of many boundaries to contend with.

Only rarely can a more or less definite and not quite arbitrary line be drawn between the territories occupied by the different races. This happens when their territories are separated from each other by some natural obstacle which is a desert or a mountain range which impedes the movement of people from one territory to the other. Suppose that we continue our voyage southward from Egypt beyond Italy. As we cross the Mediterranean Sea, the limit of North Africa proper is to be rather difficult to find. The Italians, like the Libyans, still belong to the Mediterranean branch of the white race. Further southward lies the desert of Sahara, the crossing of which used to be a difficult undertaking. In matters of fact it still is difficult, except with the aid of an airplane. Now, as soon as the Sahara is crossed, we find a new white race, whose colors are strikingly darker than those of the Libyans north of the desert. We have left the territory of the white and have entered the land of the black.

It is true that the white race is the dominant race in the world, but it is not the only race. The colored race is also a part of the human family, and it is entitled to the same rights and privileges as the white race. The colored race is not inferior to the white race, and it is not the property of the white race. The colored race is a free and independent people, and it is entitled to the same rights and privileges as the white race. The colored race is not a race of slaves, and it is not the property of the white race. The colored race is a free and independent people, and it is entitled to the same rights and privileges as the white race.

Eventually a situation is reached when as in Europe one can recognize anything from a single race to a war of races.

One might not conclude however that because the differences between races are frequently arbitrary that race is a purely arbitrary concept. By looking at a suburb in Italy one can not always be sure where the city begins and the country ends but it does not follow from this that the city exists only in imagination. Races exist regardless of whether we can easily define them or not. It is plain to see that most Norwegians can be told apart from most others. It is only appearance and this is true regardless of whether or not you decide to call them different races. Whatever your decision on this score remember that differences between races are compounded from the kind of differences that are found between individuals of the same race. A Norwegian may carry some genes and show some physical traits which are typically Italian in the sense that they are more common in Italy than in Norway. Population differences of parents of a given race do not necessarily possess all the traits which are usually met with in representatives of that race. The personal qualities of an individual are more important than the race from which he came.

Let us be very sure that we understand clearly why the barriers are so difficult an obstacle to travel between the lands of different races and become infinite rather than finite contact. When people visit each other's homes and enter they learn to know and understand and are able to like each other. One of the chief causes of the increased frequency of intermarriage in the United States and in the cities is that the natives and the immigrants are in contact with the blood of the races and appearance of intermediate or mixed racial groups. With the blood theory of heredity, however, the view that intermarriage between races leads to the eventual fusion into a single variable group is correct. In those that the race has 90 per cent of individuals of the native 10 per cent with brown eyes

Although putting the all bets on human populations  
 arbitrary procedure it is a fact that the human  
 species is not homogeneous but consists of subdivisions  
 of various orders which differ from each other in the  
 commonness of many features. Biologically the  
 divisions are quite artificial to the race or ul-  
 timate of natural or physical nature and to the breed  
 or variety of domesticated animals and cultivated  
 plants. All of these arise in the course of evolution  
 through the occurrence of mutations, gene recombina-  
 tion and natural or artificial selection of those collec-  
 tions of genes which are suited to certain environments.  
 And yet races of man have characteristics which  
 distinguish them from races of other animals. Men are  
 subject not only to local conditions but to social forces  
 and these two kinds of influences are in continual inter-  
 action with each other.

While races of wild animals and plants are kept apart  
 geographical separation alone human races may be  
 united by cultural factors. Civilized as well as primi-  
 tive man have certain religious, ethical, and political  
 ideas and the result frequently prescribes in ritual  
 union with a specific group—class, tribe, nation  
 or common religion, economic or social circle. These  
 periments different racial groups to coexist side by side  
 at least for a time in the same country.

In the same territory human racial groups may re-  
 main relatively distinct whereas in wild animals and  
 plants which reproduce exclusively usually no more than  
 a single race of a species exists in one locality. The  
 case of wild animals is not a good example. Thus  
 the members of a race are exposed to a different  
 environment and they vary with the race. Some of the  
 differences are inherited from their ancestors who in-  
 herited them from their ancestors. In a few cases  
 the differences are acquired. Others are the result of  
 the environment. It is difficult to separate the  
 inherited from the acquired. The result is a mixture  
 of the two.

regarded as propounded by partisans of this  
 in the United States is a plan to prevent the flow  
 of genes between these races by social means—custom a  
 legislation—instead of by geographical separation.  
 Milder forms of social barriers against intermarriage  
 of groups of people such as religious, economic, edu-  
 cational and language divisions may also slow down  
 the gene exchange between populations and postpone  
 for a time the obliteration of the races. But the long-  
 time trend is clearly toward race fusion.

Contrary to the opinion vociferously expressed by  
 some sincere but misguided people such a trend is no  
 biologically dangerous. Mixing of closely related  
 may even lead to increased vigor. As for the most  
 tantly purified races there is no basis in fact to think  
 that either physical stimulation or deterioration fol-  
 lows crossing. The widespread belief that human  
 hybrids are inferior to both of their parents and some-  
 how constitutionally unbalanced must be counted  
 among the superstitions.

### *Do Human Races Differ in Mental Capacity?*

Breeds of dogs differ markedly in temperament  
 responsiveness to particular kinds of training and he-  
 in the use to which they may best be put by man. Al-  
 though almost any dog can be trained when young to  
 be of some use one would not for choice try to train  
 a dachshund to be a sheep herder or a shepherd  
 to hunt rabbits. Similarly the differences in temper-  
 ment between polo ponies and draft horses which are  
 certainly conditioned in part by their heredity fit them  
 for different functions. These breed differences have  
 been accentuated by selective breeding by men who  
 have selected the fittest in a few. It has often been  
 argued that the differences in biological inheritance  
 lie at the bottom of intellectual, emotional and tem-  
 peramental differences between races and between cul-  
 tures.

Another objection is as follows. Races arise as

and so

part of the evolutionary process by which populations within a species become adapted to a particular environment. I shall vary on in skin color has for example been viewed in this way. If biological evolution has caused races of man to diverge in physical characters should it not have done the same for the mental capacities and aptitudes of the people?

Both of these arguments by analogy are unconvincing. The first is based on a misunderstanding of the nature of biological heredity. It has been pointed out repeatedly in this book that what is inherited is not the trait but the manner in which the development of an organism responds to its environment. Now the amount as well as the kind of variation which a trait shows in different environments is decided by the hereditary make up of the organism. For example individuals who carry the genes for the O A or B blood groups have the respective blood groups regardless of their state of health, the climate they live in or the nutrition which they receive. The blood group is rigidly fixed by heredity. But the skin color is not so rigidly fixed. It is not so rigidly fixed but it is rather rapidly dependent on the nature of the skin to which it is applied, whether or not an individual gets into conflict with the environment, upon the person's upbringing and circumstances and also upon the kind of laws which the society sees fit to establish. Human behavior is then quite plastic and can be changed by the living conditions.

The important problem why our traits are more or less fixed or plastic is not a matter of heredity but of adaptation. By the way the traits which are important for the survival of the individual are those which are peculiar to a race or a group. The traits which are important for the development of the individual are those which are inherited from the parents. The traits which are important for the survival of the individual are those which are inherited from the parents. The traits which are important for the survival of the individual are those which are inherited from the parents.

But it is also advantageous for the safety of the organism to have some traits change rather easily when the environment changes. For example dark skin pigmentation is advantageous during summer vacation on the seashore. But little skin pigment is supposedly advantageous to secure a supply of vitamin D (the sunlight vitamin) when sunlight is scarce. The genetic constitution which is most favorable in a changeable climate is then one which permits the development of darker or lighter skin colors at different seasons and in different climates.

The relative fixity of the temperamental make up of horse or dog breeds is then understandable. These breeds have been fashioned by man and intended for different uses. A great Dane with the temper of a fox terrier might be dangerous and a fox terrier with the temperament of a great Dane would be boring. The genetic component is important in the temperament of these breeds. It has been made important by selection and breeding. But has there been a similar selection in the evolution of man?

It is possible that different social positions and different trade call for somewhat different behavior patterns. The qualities most useful in a military leader are not the same which are most favored in a writer or a scientist and vice versa. The mentality of a nomadic hunter is usually different from that of a farmer. But the present requirements of living in any human society are very nearly the same. It is the ability to learn from experience and to list one's behavior to the needs and circumstances. This requirement is fundamental for living in any culture or civilization from the most primitive to the most complex. Accordingly the process of selection which has been and still is not powerful as it is present in human evolution. It is for the ability to learn new ways of behavior, new techniques of doing things and new skills.

In the present human species as a whole has developed a very great genetic plasticity and fixity of behavior and toward education. This is true for all races of

man and for all climates. Therein lies the most important biological feature of the evolutionary pattern of mankind. The likes of us or of horses have been selected for performance of these services by making their genes different. Man is certainly capable of pursuing a great variety of ways of life. But he is enabled to do so by different training and education, not by requiring different genes. Thus does not mean that the genetic differences among men do not affect their mentality. But from the vantage point of evolutionary biology we can see that such differences are not fundamental. Far more important is the fact that human capacities are developed by training from childhood on. In those cases aside human personality is shaped mainly by the patterns of interpersonal relations which prevail in a given culture, and by the individual experiences of each member of a community. Thus genetically conditioned educability has guaranteed the success of mankind as a biological species, and in this process progressively more advanced cultural development.

### Cultural Progress

Although universal uniformity of men appeals to some people, there is no reason why monotonous sameness should be our goal. On the contrary, such a prospect appears bleak in the extreme. Psychological and cultural differences among individuals and groups furnish the leverage of creative effort which carries mankind toward ever greater achievements. The quest on of whether or not human races differ in hereditary psychomotor traits for the time being must be regarded as of secondary importance. We know that a variety of different cultural values exist in the world. The differences between them can only be not be considered for the sake of the individual. It is the group of individuals which is the unit of cultural development. It is the group which is the unit of cultural development. It is the group which is the unit of cultural development.

There is to an extent assuredly greater than be insisted by biological heredity. Further differences between individuals are certainly greater than the average differences between races.

We have seen that the psychic trait which is most favored in human evolution is ability to profit from experience. The educational ability does not make all men alike. The opposite is true. The survival advantage of to learn and to be trained consists precisely in development of a person can be turned in many possible directions as necessity may demand. It permits then a vastly greater diversity of human personalities than could possibly arise if they were genetically fixed as it is in the inhabitants of the anthill. Far from mental uniformity human evolution has been moving diversity.

Regardless of how the problem of the intellectual heredity is handled and of the choice of culture may eventually be a variety of human cultures will appear to us rather than a curse if we learn to understand and to admire them. In the real there is enough room to accommodate the contrasts not only of different individuals but of nations and race. It is a waste of energy which particular contributions are which hinder or there is no common measure to the works of a poet, an artist, a philosopher and the simple kindness of heart of a human being needs them all.

## Appendix

### Why Do the Positions of Dominant and Recessive Genes in a Population Remain Con- stant from Generation to Generation?

Suppose that a previously uninhabited island or other  
 unoccupied and isolated spot of land populated by  
 a group of immigrants from there are as many  
 individuals as there are those who can not taste the  
 T allele. The ability to taste T is as we  
 know inherited from the ability to taste it to the  
 extent of the difference between the two (no homo-  
 zygous) for the allele (T) is the gene T for taste

len want to find out the not  
steps are a better design (it) What propor  
tions of factors will be found in the  
population of the next and all follo

... it does not matter for people  
... or can not taste ITC and

fact very few people know to which of these is correct. They tell me the ability or inability to taste this bitter stuff affects the inheritance of color among the Chinese. I have seen a Chinese man who has a taste for

chances that a taster  
will be deter-

I imply by the proportion of the tasters and  
 out tasters in the eligible mates if so the married  
 the national proportions like also as follows

Of the men who are tasters about half will  
 1 t 3 and half n n tasters of the men who are n  
 t t t t out half s all marry tasters and half non t  
 This means that of all marriages about 1/4 n  
 ho h tasters about 1/2 are mixed marriages and  
 about 1/4 both partners are non tasters If tasters  
 non tasters live about equally long and have about  
 the same number of children the first generation of c  
 dren will consist of 1/4 pure tasters TT 1/2  
 tasters Tt and 1/4 pure non tasters tt or in other  
 words 75 per cent tasters and 25 per cent non

Now we want to know what kind of children children will have if marriages amongst them take it random with respect to the alidity to (TT, Tt and tt) and the same three kinds of sex the proportions  $\frac{1}{4}$   $\frac{1}{4}$   $\frac{1}{4}$ . The possible combinations of males and females and the children expected in the marriage if four children are born from a marriage will be as follows

M	W	cc	i	e	i	ca	CH	
1 TT	1/2 TT		1/10				1 TT	
1 TF	1/2 FT		1/10				1 TT	1 Tt
1/4 TT	1/4 TT		1/10					4 Tt
1 Tt	1/4 TT		2/10				4 TT	1 Tt
1/2 Ft	1/2 Ft		4/10				1 FF	8 Ft
1 Tt	1/4 TT		1/10					1 Ft
1 tt	1/4 FF		1/10					1 Ft
1 tt	1/2 Ft		7/10					1 Ft
1 tt	1/2 tt		1/10					
						Totals	16 TT	32 Tt

The children will again appear with pre-  
sented. There will be no more of the  
the effect of the non-tasters. They will  
be as they were among the p-  
the can be reached in a d-

The same conclusion can be reached in a different way. Instead of considering the random mating, the members of the population we can think
